### Major components of approaching MDP

- (policy evaluation) We need to be able to evaluate  $V^{\pi}(s)$  for a fixed  $\pi$ . This is called *policy evaluation*. This is also called as *prediction* in reinforcement learning.
- ② (optimal value function) We want to be able to evaluate  $V^{\pi^*}(s)$ , where  $\pi^*$  is the optimal policy. The quantity,  $V^{\pi^*}(s)$ , is optimal policy's value function, or called shortly as optimal value function.
- (optimal policy) We want to find the optimal policy  $\pi^*$ . This is also called as control in reinforcement learning
  - Check your reasoning why the followings are possible.
    - Optimal policy first: (optimal policy) + (policy evaluation) → (optimal value function)
    - Optimal value function first: (optimal value function)  $\rightarrow$  (optimal policy)
  - This note will discuss

I. Recap 0000

• (policy evaluation) + series of (policy improvement)  $\rightarrow$  (optimal policy)

## II. Policy improvement

### Development

Remind that we have a Bellman's equation for MDP as follows.

$$V^{\pi}(s) = R^{\pi}(s) + \gamma \sum_{\forall s'} \mathbf{P}^{\pi}_{ss'} V^{\pi}(s') \quad \text{(E1, p18)}$$

- It means that, given a π, its value is determined by immediate reward plus discounted sum of future reward.
- ullet In this light, let's try to criticize the  $\pi_{speed}$ .

```
t(policy_eval(pi_speed))
## 0 10 20 30 40 50 60 70
## [1,] -5.805929 -5.208781 -4.139262 -3.475765 -2.35376 -1.735376 -1.673538 0
```

- From the state 60, current policy gives the estimate for the state-value function of -1.6735376.
- We know that switching to *normal mode* at state 60 is better alternative than current action of *speed mode*. Because it guarantess the arrival to the state 70 with additional energy spending of 1.0.
- How would you express this fact in a mathematical form?

- ullet Under the current policy's  $(\pi_{speed})$  value function, on the state 60,
  - Choosing normal mode gives

$$R + \gamma \mathbf{P}V = -1.0 + 1.0 \cdot 0 = -1.0$$

• Choosing speed mode gives

$$R + \gamma \mathbf{P}V = -1.5 + (0.9 \cdot 0 + 0.1 \cdot -2.6) = -1.76$$

- ullet This,  $\pi_{speed}$  should modify its action on the state 60.
- ullet You just improved the current policy  $\pi_{speed}$  for the state 60!
- This should be checked for all states as well as the state 60.
- This completes policy improvement.
- Formally, policy improvement implies the following task of replacement:

$$\pi^{new}(s) \leftarrow argmax_{a \in \mathcal{A}} \left\lceil R(s, a) + \gamma \sum_{\forall s'} P^a_{ss'} V^{\pi^{old}}(s') \right\rceil, \text{ for all } s$$

$$\pi^{new}(s) \leftarrow argmax_{a \in \mathcal{A}} \left[ R(s, a) + \gamma \sum_{\forall s'} P^a_{ss'} V^{\pi^{old}}(s') \right], \text{ for all } s$$

- The term in the RHS,  $R(s,a) + \gamma \sum_{\forall s'} P^a_{ss'} V^{\pi^{old}}(s')$ , implies [an expected return of starting from state s, choosing an action a for this time step only, then following the policy  $\pi$  afterwards.].
- How is this quantity different from  $V^{\pi}(s)$ ?

- The RHS makes an improvement using current policy  $\pi$ , by varying only the action in this time step.
- ullet Formally, q(s,a) is called **action-value function**, also famously known as Q-function.

$$\begin{array}{lcl} q(s,a) &:= & \mathbb{E}_{\pi}[G_t|S_t=s,A_t=a] \\ &= & R(s,a) + \gamma \sum_{\forall s'} P^a_{ss'} V^{\pi^{old}}(s') \end{array}$$

$$\pi^{new}(s) \leftarrow argmax_{a \in \mathcal{A}} \left[ R(s, a) + \gamma \sum_{\forall s'} P^a_{ss'} V^{\pi^{old}}(s') \right], \text{ for all } s$$

• Using this new notation of q(s, a), the policy improvement can be written as

$$\pi^{new}(s) \leftarrow argmax_{a \in \mathcal{A}} \; q(s,a), \; \text{for all } s$$

- The improvement is called *greedy improvement* since it involves a myopic digression from the current policy, in a way that an action only on this time step is revised.
- It can be proved that *greedy improvement* is guaranteed to improve.

### **Implementation**

$$\pi^{\textit{new}}(s) \leftarrow argmax_{\textit{a} \in \mathcal{A}} \left[ R(s, \textit{a}) + \gamma \sum_{\forall s'} \mathbf{P}^{\textit{a}}_{ss'} V^{\pi^{\textit{old}}}(s') \right], \text{ for all } s$$

```

## III. Policy iteration

#### Discussion

- Given a policy  $\pi$ , policy\_eval() evaluates its state-value function.
- Using the estimate of state-value function, policy\_improe() improves the policy to the better one.
- If this process is iterated, then it is guaranteed to reach optimal policy.
- In other words, policy iteration is the process to reach the optimal policy described as follows.

$$\begin{split} \pi_0 & \xrightarrow{\text{policy\_eval()}} V_0 \xrightarrow{\text{policy\_improve()}} \pi_1 \xrightarrow{\text{policy\_eval()}} V_1 \xrightarrow{\text{policy\_improve()}} \\ \pi_2 & \to \cdots \to \cdots \to \pi^* \xrightarrow{\text{policy\_eval()}} V^* (= V^{\pi^*}, \text{ for short.}) \end{split}$$

- The iteration process terminates when  $\pi_i$  does not change any more, i.e.  $\pi_i = \pi_{i+1}$ .
- Note that policy evaluation is an approximate algorithm. For policy iteration purpose, policy evaluation cannot be, (and doesn't have to be as well), perfect.

# Try do it over and over until no change - from $\pi^{speed}$

#### • Step 0

```
pi old <- pi speed
pi old
##
      normal speed
            0
## A
                  1
                  1
## 10
## 20
                  1
## 30
            0
                  1
                  1
## 40
## 50
                  1
## 60
            0
                  1
## 70
            0
                  1
```

### • Step 1

```
V_old <- policy_eval(pi_old)
pi_new <- policy_improve(V_old,
    pi_old = pi_old, R_s_a = R_s_a, gamma = gamma,
    P_normal = P_normal, P_speed = P_speed)
pi_old <- pi_new
pi_old
## normal speed</pre>
```

```
## 0
## 10
                  0
## 20
                  1
## 30
                  0
## 40
                  0
## 50
                  1
            1
## 60
                  a
## 70
            1
                  0
```

##

#### Step 2

```
V_old <- policy_eval(pi_old)
pi_new <- policy_improve(V_old,
    pi_old = pi_old, R_s_a = R_s_a, gamma = gamma,
    P_normal = P_normal, P_speed = P_speed)
pi_old <- pi_new
pi_old</pre>
```

## 0	0	1	
## 10	0	1	
## 20	0	1	
## 30	1	0	
## 40	1	0	
## 50	0	1	
## 60	1	0	
## 70	1	0	

normal speed

### • Step 3

```
V_old <- policy_eval(pi_old)
pi_new <- policy_improve(V_old,
    pi_old = pi_old, R_s_a = R_s_a, gamma = gamma,
    P_normal = P_normal, P_speed = P_speed)
pi_old <- pi_new
pi_old</pre>
```

##		normal	speed
##	0	0	1
##	10	0	1
##	20	0	1
##	30	1	0
##	40	1	0
##	50	0	1
##	60	1	0
##	70	1	0

# Policy iteration process (from $\pi^{speed}$ )

 Now we are ready to implement whole process as a single code block.

```
pi old <- pi speed
cnt <- 0
repeat{ # do-while in R
  print(paste0(cnt, "-th iteration"))
 print(t(pi old))
 V old <- policy eval(pi old)
  pi new <- policy improve(V old,
    pi_old = pi_old, R_s_a = R_s_a, gamma = gamma, ## speed 1 1 1 0 0
    P normal = P normal, P speed = P speed)
 if (all.equal(pi_new, pi_old)==TRUE) break
  pi old <- pi new
  cnt <- cnt + 1
print(policy eval(pi new))
```
